### **ABSTRACT**

deviance to auditory language tissue development. We find that early, but not cochlear implants (CI)1.2.3.4. Noteworthy are claims that due to neuroplasticity of experience on the acquisition of spoken language in deaf individuals with later, exposure to a signed language supports typical language development. auditory language tissue, early exposure to a signed language results in Controversy abounds regarding the specific impact of differences in language

Inferior Frontal Gyrus (LIFG) and Superior Temporal Gyrus (STG)5.6.7 in a deaf individual with a CI? nemisphere spoken language tissue development, including left Does early exposure to a visual signed language impact classic left-

in the deaf CI individual? Does age of signed language exposure impact language processing

### **HYPOTHESES**

- H1 Early language exposure, both signed and spoken, facilitates normal neural development for language processing
- P1 CI individual with early, but not later, signed language exposure recruit left-hemisphere language areas
- **H**2 Only early spoken language exposure facilitates normal neural Early signed language exposure disrupts development development for language processing
- P2 CI individual with early and later signed language exposure do not recruit left-hemisphere language areas

.ater-exposed > Early-Exposed lon Significant

#### METHODS

Deaf Adults with cochlear implant (Age of Implant = 13 years)

Early Signed Language Exposure (ASL before age 5 years) N = 4 Later Signed Language Exposure (ASL after age 5 years) N = 4

Word Reading<sup>10</sup> in English

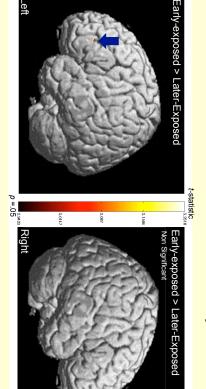

Reading aloud English words is safe for cochlear implant Near Infrared Spectroscopy (fNIRS) neuroimaging<sup>8,9</sup> Advancement: Optical imaging Regular *stop* 

Irregular debt

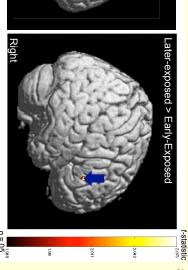

Nonsense

RESULTS

# Early Signed Language Exposed Deaf Cl Individuals Show Greater Neural Activation in Left Inferior Frontal Gyrus

# Later Signed Language Exposed Deaf Cl Individuals Show Greater **Neural Activation in Right Inferior Frontal Gyrus**

### CONCLUSION

activation in classic left-hemisphere language areas Early exposed deaf CI individuals showed greater

classic left hemisphere language areas (LIFG) activation in the right-hemisphere (RIFG), not in Late exposed deaf CI individuals showed greater

## Supports Hypothesis 1

Early signed language exposure facilitates normal language processing

No evidence of a negative impact on language processing as a result of early visual signed language exposure

#### Implications

Optimal developmental timing of

signed language exposure

Early language exposure, be it signed or spoken supports healthy, typical language development

facilitate language processing in the deaf CI individual New view on how early life language exposure, irrespective of modality (signed, spoken), can
